S1 Introduction

2

This is the supplementary material to the research paper "A Comparison of Chemical Mechanisms using Tagged Ozone Production Potential (TOPP) Analysis" and provides further information about the methodology as well as additional analysis.

S2 Mechanism Setup

All chemical mechanisms were adapted from their original format into the modularised KPP (Damian et al., 2002) format for use in the MECCA boxmodel (Sander et al., 2005) as modified by (Butler et al., 2011).

The MCM v3.2 (Jenkin et al., 1997, 2003; Saunders et al., 2003; Bloss et al., 2005;
Rickard et al., 2015) is the reference mechanism and its approach to dry deposition,
photolysis and peroxy radical-peroxy radical reactions were applied to all mechanisms.

8 S2.1 Photolysis

Photolysis was parameterised as a function of the solar zenith angle following the MCM approach (Saunders et al., 2003). Species from reduced mechanisms with a direct

counterpart in the MCM v3.2 were assigned the corresponding MCM v3.2 photolysis rate parameter. Otherwise, the recommended rate parameter in the mechanism determined the appropriate MCM v3.2 photolysis rate parameter. In some cases, the MCM v3.2 photolysis rate parameter closest in magnitude to that specified by the mechanism was used. For example, the organic nitrate species ONIT in RACM2 has a photolysis rate parameter of 1.96 × 10⁻⁶ s⁻¹ that was compared to the MCM v3.2 organic nitrate photolysis rate parameters (J₅₁ – J₅₇). The rate parameter J₅₄ is the most similar in magnitude and was assigned as the ONIT photolysis rate parameter in RACM2.

Photolysis reactions of a species in reduced mechanisms were sometimes represented

by more than one MCM v3.2 photolysis reaction. The product yields of the original

mechanism reactions were preserved using combinations of the MCM v3.2 rate parameters.

For example, glyoxal photolysis described by (R1) and (R2) in RADM2.

$$GLY + h\nu \longrightarrow 0.13 \text{ HCHO} + 1.87 \text{ CO} + 0.87 \text{ H}_2$$
 (R1)

$$\mathrm{GLY} + \mathrm{h}\nu \ \longrightarrow \ 0.45 \ \mathrm{HCHO} + 1.55 \ \mathrm{CO} + 0.8 \ \mathrm{HO}_2 + 0.15 \ \mathrm{H}_2 \quad \mathrm{(R2)}$$

Whereas in the MCM v3.2, (R3), (R4) and (R5) are prescribed for glyoxal photolysis with the rates J_{31} , J_{32} and J_{33} .

$$GLYOX + h\nu \longrightarrow 2 CO + 2 H_2$$
 (R3)

$$\mathrm{GLYOX} + \mathrm{h}\nu \ \longrightarrow \ 2 \ \mathrm{CO} \, + \, 2 \ \mathrm{HO}_2 \quad \mathrm{(R4)}$$

$$GLYOX + h\nu \longrightarrow HCHO + CO$$
 (R5)

The product yields in (R1) were retained using a photolysis rate parameter of $0.87 J_{31} + 0.13 J_{32}$, whilst for (R2) the rate $0.15 J_{31} + 0.45 J_{32} + 0.4 J_{33}$ was used. Table S1 illustrates the product yield calculations.

40 S2.2 Organic Peroxy Radical Self and Cross Reactions

36

Reactions of organic peroxy radicals (RO₂) with other organic peroxy radicals are divided into self (RO₂ + RO₂) and cross (RO₂ + R'O₂) reactions. These reactions are typically represented in chemical mechanisms as bimolecular reactions which would cause ambiguities when implementing the tagging scheme. Namely, which tag to be used for the products of reactions between RO₂ reactants having different tags. The MCM v3.2 approach to self and cross RO₂ reactions (each RO₂ species reacts with the pool of all

	Rate Parameter	MCM v3.2 Products and Yields
	$0.87 \mathrm{J}_{31}$	$1.74~{\rm CO} + 0.87~{\rm H}_2$
(R1)	$0.13 \mathrm{J}_{32}$	$0.13~{ m CO}+0.13~{ m HCHO}$
	$0.87~{ m J}_{31}+0.13~{ m J}_{32}$	$1.87~{\rm CO}+0.13~{\rm HCHO}+0.87~{\rm H}_2$
	$0.15 \mathrm{J}_{31}$	$0.30~{\rm CO}+0.15~{\rm H}_2$
(R2)	$0.45 \mathrm{J}_{32}$	$0.45~\mathrm{CO}+0.45~\mathrm{HCHO}$
(112)	$0.4 \mathrm{J}_{33}$	$0.80~{\rm CO}+0.80~{\rm HO_2}$
	$\overline{ m 0.15~J_{31}+0.45~J_{32}+0.4~J_{33}}$	$1.55~{\rm CO} + 0.45~{\rm HCHO} + 0.80~{\rm HO}_2 + 0.15~{\rm H}_2$

Table S1: Calculation of glyoxal MCM v3.2 photolysis rate parameters retaining RADM2 glyoxal photolysis product yields.

Mechanism	Reaction	Rate Constant
	C2H5O2 = C2H5O	$k*RO2*0.6 s^{-1}$

	$\begin{array}{l} {\rm C2H5O2+C2H5O2} = 1.6{\rm CH3CHO}+1.2{\rm HO2} \\ +0.4{\rm C2H5OH} \end{array}$	$6.8 \times 10^{-14} \text{ cm}^3$ molecules ⁻¹ s ⁻¹
MOZART-4 modified	$ ext{C2H5O2} = 0.8 \text{ CH3CHO} + 0.6 \text{ HO2} + 0.2 \text{ C2H5OH}$	$2 \times 10^{-13} * RO2 s^{-1}$

Table S2: Ethyl peroxy radical $(C_2H_5O_2)$ self and cross organic peroxy reactions in MCM v3.2 and MOZART-4 including rate constants. $k=2(6.6\times 10^{-27}\exp(365/T))^{\frac{1}{2}}$ molecules⁻¹ s⁻¹ and RO2 is the sum of all organic peroxy radical mixing ratios.

Reactants	Products	Rate Constant
MO2 + MO2	$0.74~{\rm HO2}+1.37~{\rm HCHO}+0.63~{\rm MOH}$	$9.4 \times 10^{-14} \exp{(390/T)}$
WO2 + WO2		$\mathrm{cm^3\ molecules^{-1}\ s^{-1}}$
MO2	$0.37~{\rm HO2}+0.685~{\rm HCHO}+0.315~{\rm MOH}$	$9.4 \times 10^{-14} \exp{(390/T)} * RO2$
WIOZ		s^{-1}
$\overline{\text{ETHP} + \text{MO2}}$	$ m HO2+0.75\;HCHO+0.75\;ACD$	$1.18 \times 10^{-13} \exp{(158/T)}$
ETIII + MOZ	$+~0.25~\mathrm{MOH}~+~0.25~\mathrm{EOH}$	$\mathrm{cm^3\ molecules^{-1}\ s^{-1}}$
ETHP	$0.63~{\rm HO2}+0.065~{\rm HCHO}+0.75~{\rm ACD}$	$1.18 \times 10^{-13} \exp{(158/T)} * RO2$
	$+~0.25~{ m EOH}$	s^{-1}

Table S3: Dermination of ETHP pseudo-unimolecular reaction and rate constant in RACM2 including rate constants. RO2 is the sum of all organic peroxy radical mixing ratios.

other RO₂ at a single uniform rate) is used to avoid such ambiguities. The MCM v3.2
approach represents RO₂-RO₂ reactions as a pseudo-unimolecular reaction whose rate
constant includes a factor 'RO2' which is the sum of the mixing ratios of all organic peroxy
radicals (Saunders et al., 2003).

The pseudo-unimolecular reaction products and their yields were determined by one of two methods. Firstly, by using the $RO_2 + RO_2$ reaction and halving the product yields, demonstrated for the MOZART-4 treatment of the ethyl peroxy radical in Table S2.

- Alternatively, the RO₂+CH₃O₂ reaction was used to determine the products due to CH₃O₂ and these products are then removed.
- Table S3 demonstrates the steps determining the ETHP pseudo-unimolecular reaction in RACM2. First the products due to MO2 (CH₃O₂ in RACM2) are determined as outlined previously using the MO2 + MO2 reaction. The MO2 product yields are subtracted from the ETHP + MO2 reaction. Any products having a negative yield are not included in the final pseudo-unimolecular reaction.

The methyl acyl peroxy radical $(CH_3C(O)O_2)$ was the exception to the above approach. Although most mechanisms include a $CH_3C(O)O_2 + CH_3C(O)O_2$ reaction, the $CH_3C(O)O_2$ pseudo-unimolecular reaction was derived by subtracting the CH_3O_2 product yields from the $CH_3C(O)O_2 + CH_3O_2$ reaction. This approach was used as the $CH_3C(O)O_2 + CH_3O_2$ reaction is the most significant reaction for $CH_3C(O)O_2$.

- The rate constant for each pseudo-unimolecular reaction was taken as that of the $RO_2 + CH_3O_2$ reaction multiplied by an 'RO2' factor, which is the sum of the mixing ratios of all organic peroxy radicals. The $RO_2 + CH_3O_2$ rate constant was chosen as this is the most likely reaction to occur.
- Model runs using the original and modified approach to the RO₂-RO₂ reactions for each mechanism were performed. The resulting O₃ concentration time series were compared and shown in Figure S1.

S2.3 Dry Deposition

Dry deposition velocities for individual chemical species are taken from the MCM v3.2. The MCM v3.2 dry deposition velocities of the same chemical functional group were used for mechanism species without direct MCM v3.2 analogues. For example, the dry deposition

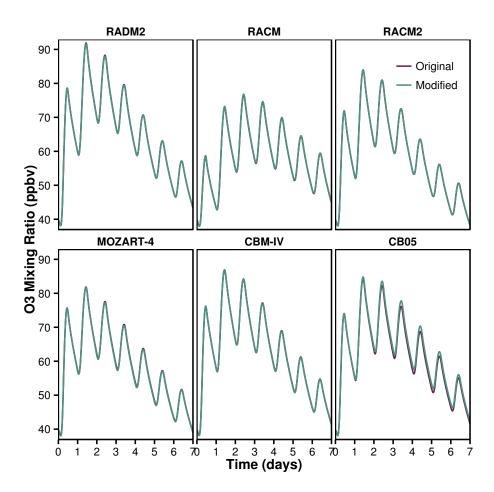

Figure S1: O_3 mixing ratio time series for each reduced mechanism using the original and modified approach to RO_2 – RO_2 reactions

velocity of PAN-like species in all mechanisms was equivalent to that of the PAN species in the MCM v3.2.

S2.4 Negative Product Yield Treatment

- Some mechanisms include reactions where products have a negative yield. These reactions were re-written including an operator species with a positive yield as the analysis tools
- used in this study do not allow negative product yields. The operator species acts as a sink for the original product by immediately reacting with the original product generating
- 84 a 'NULL' product.

For example, in RADM2 the OH + CSL (cresol) reaction has negative OH yield in (R6) (Stockwell et al., 1990).

$$\mathrm{CSL} + \mathrm{OH} \ \longrightarrow \ 0.1 \ \mathrm{HO_2} + 0.9 \ \mathrm{XO_2} + 0.9 \ \mathrm{TCO_3} \ \text{-} \ 0.9 \ \mathrm{OH} \ \ (\mathrm{R6})$$

The negative OH yield was adapted to a positive operator (OHOP) yield in (R7). OHOP then reacts immediately with OH giving a 'NULL' product with a rate constant of 8.0 × 10⁻¹¹ cm³ s⁻¹ (R8). Thus preserving the OH yields from (R6) in RADM2.

$$\mathrm{CSL} + \mathrm{OH} \quad \longrightarrow \quad 0.1 \; \mathrm{HO_2} \, + \, 0.9 \; \mathrm{XO_2} \, + \, 0.9 \; \mathrm{TCO_3} \, + \, 0.9 \; \mathrm{OHOP} \quad (\mathrm{R7})$$

$$OHOP + OH \longrightarrow NULL$$
 (R8)

92 S3 Mapping Emitted NMVOC to Mechanism Species

The emitted NMVOC are typical of Los Angeles as described in Baker et al. (2008). The MCM v3.2, v3.1 (Jenkin et al., 1997; Saunders et al., 2003; Jenkin et al., 2003) and CRI v2 (Jenkin et al., 2008) explicitly represent all of these NMVOC.

- NMVOC representation in all other mechanisms required mapping to specific mechanism species. This mapping followed the recommendations on the literature of the mechanism; Table S4 describes the mechanism species used for mapping the initial NMVOC. Table 2 of the main article shows the final mapping of each NMVOC to each
- 100 mechanism species.

Mechanism	Species	Description	Mechanism	Species	Description
	C2H6	Ethane		ETH	Ethane
	C3H8	Propane		HC3	OH rate constant (298 K, 1 atm) less than 3.4×10^{-12} $\rm cm^3~s^{-1}$
MOZART-4 (Emmons	BIGALK	Lumped alkanes C $>$ 3		HC5	OH rate constant (298 K, 1 atm) between 3.4×10^{-12} and 6.8×10^{-12} cm 3 s $^{-1}$
et al., 2010)	C2H4	Ethene	m RACM2	HC8	OH rate constant (298 K, 1 atm) greater than $6.8\times10^{-12}~{\rm cm}^3~{\rm s}^{-1}$

Table S4: Description of primary mechanism species used for mapping emitted NMVOCs.

S4 Treatment of 2-methylpropene Degradation

Figure 4 of the main article shows the first day TOPP values of the VOC obtained in each reduced mechanism compared to the MCM v3.2. The first day TOPP values of 2-methylpropene in RACM, RACM2, MOZART-4, CBM-IV and CB05 signify differences in its degradation to the MCM v3.2.

The variation between RACM, RACM2 and MCM v3.2 arises from differences in the ozonolysis rate constant of 2-methylpropene. This rate constant is an order of magnitude faster in RACM and RACM2 than in MCM v3.2 as the RACM, RACM2 rate constant is a weighted mean of the ozonolysis rate constants of each VOC represented as OLI (Stockwell et al., 1997; Goliff et al., 2013). The faster rate constant promotes increased radical production leading to more O_x in RACM and RACM2 than the MCM v3.2.

2-methylpropene is represented as BIGENE in MOZART-4. The degradation of BIGENE produces CH₃CHO through the reaction between NO and the 2-methylpropene peroxy radical, whereas no CH₃CHO is produced during 2-methylpropene degradation in the MCM v3.2. CH₃CHO initiates a degradation chain producing O_x involving CH₃CO₃ and CH₃O₂ leading to more O_x in MOZART-4 than MCM v3.2.

CBM-IV and CB05 represent 2-methylpropene as a combination of aldehydes and PAR, the C-C bond (Gery et al., 1989; Yarwood et al., 2005). This representation of 2-methylpropene does not produce the 2-methylpropene peroxy radical, whose reaction with NO is the main source of O_x production in all other mechanisms.
